

Aurora Analytics Platform — Release Notes

v3.2.0, released 12 March 2026

FICTIONAL DOCUMENT — created for demo and testing purposes only. Aurora Analytics Platform is not a real product.

Overview

Aurora Analytics Platform v3.2.0 is a feature release focused on faster exploratory analysis and always-on dashboards. This release supersedes the previous release, v3.1.4, and is a recommended upgrade for all self-hosted and cloud customers. Version 3.2.0 was released on 12 March 2026.

New Features

This release introduces four named features:

- **Cohort Explorer** — build and compare user cohorts visually without writing SQL.
- **Live Dashboards** — dashboards that refresh continuously as new events arrive.
- **Query Profiler** — per-query timing breakdowns to diagnose slow reports.
- **Scheduled Exports** — deliver CSV snapshots to a destination on a fixed schedule.

The default query timeout in v3.2.0 is set by the configuration value **QUERY_TIMEOUT = 30s**.

Queries that exceed 30 seconds are cancelled and return a timeout error. Administrators can raise this limit per workspace.

New Features (continued)

Cohort Explorer and Live Dashboards are enabled by default for all workspaces on v3.2.0. Query Profiler is opt-in and must be turned on per project by a workspace administrator. Scheduled Exports supports a maximum of 50 scheduled jobs per workspace.

Bug Fixes

The following defects were resolved in v3.2.0:

- **ERR-4021** — fixed a dashboard export failure that caused large PDF exports to abort partway through. Dashboard exports now complete reliably regardless of size.
- **ERR-3350** — fixed a timezone drift bug where scheduled reports ran one hour off after daylight-saving transitions. Scheduled report times are now stable across DST.
- **ERR-2907** — fixed a rendering glitch where stacked bar charts dropped the final series in the legend.
- **ERR-1188** — fixed an issue where saved filters were not applied on first dashboard load.

System Requirements

To run Aurora Analytics Platform v3.2.0, the following minimum requirements apply:

- **Minimum RAM: 16 GB** for the application server (32 GB recommended for production).
- Supported browsers: **Google Chrome, Mozilla Firefox, and Microsoft Edge. Safari is not supported** in v3.2.0.
- Database: **PostgreSQL 14 or later** (Postgres 14+). Earlier Postgres versions are not supported.
- Disk: 50 GB free for the event store.

Deprecations

The **legacy v2 REST API is deprecated** as of v3.2.0 and will continue to function throughout the v3.x series. The v2 REST API will be **removed in v4.0**. Integrations should migrate to the v3 API before the v4.0 upgrade.

Known Issues

- Live Dashboards may briefly show a stale value for up to 5 seconds immediately after a workspace is first created; the value corrects itself on the next refresh.
- Cohort Explorer comparisons of more than 20 cohorts at once can render slowly on the application server minimum of 16 GB RAM.

Known Issues (continued)

Both known issues listed above are scheduled for follow-up fixes in a future v3.2.x patch release. No workaround is required for the Live Dashboards stale-value issue; it resolves automatically.

Upgrade Notes

Upgrading from v3.1.4 to v3.2.0 requires no schema migration and can be performed in place.

Administrators should confirm their database is on PostgreSQL 14+ and that the application server meets the 16 GB minimum RAM requirement before upgrading.

End of release notes for Aurora Analytics Platform v3.2.0 (fictional).
